Chapter 3 Transport Layer

Computer Networking: A Top-Down Approach

8th edition Jim Kurose, Keith Ross Pearson, 2020

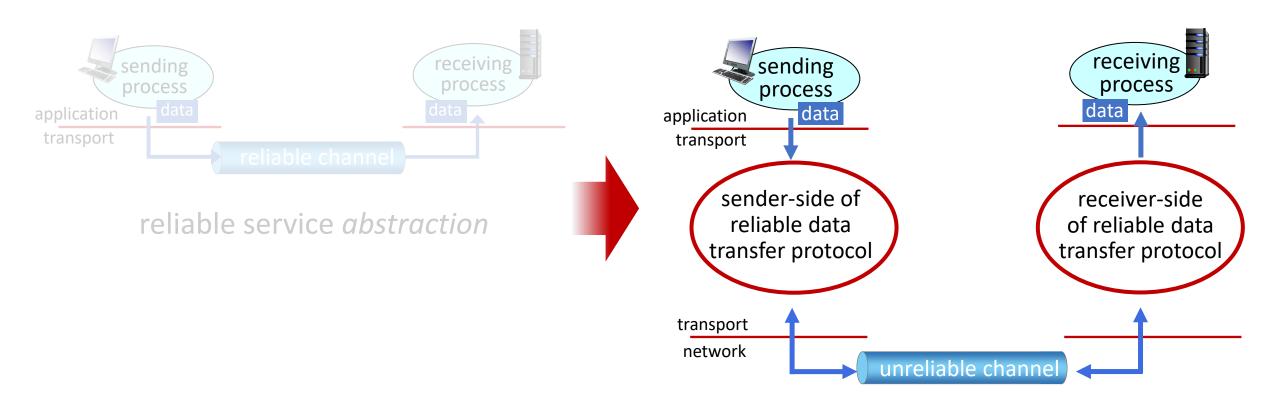

Chapter 3: roadmap

- Transport-layer services
- Multiplexing and demultiplexing
- Connectionless transport: UDP
- Principles of reliable data transfer
- Connection-oriented transport: TCP
- Principles of congestion control
- TCP congestion control
- Evolution of transport-layer functionality

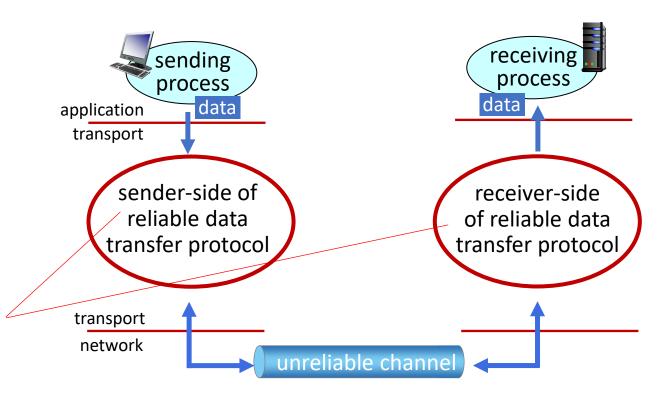

reliable service abstraction

reliable service implementation

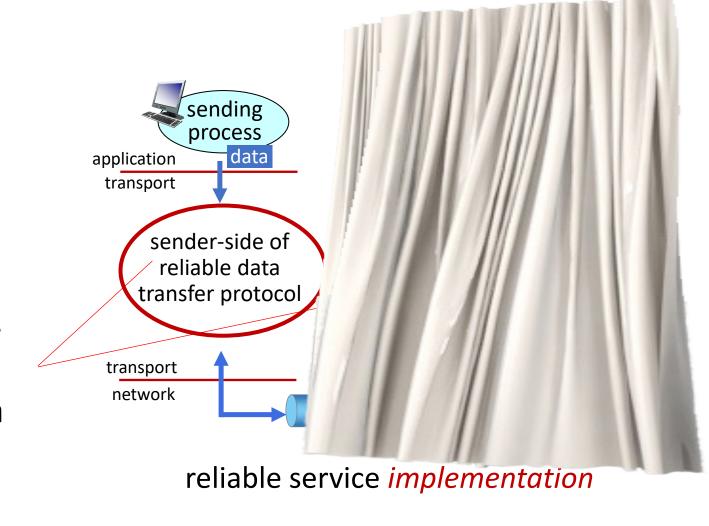

Complexity of reliable data transfer protocol will depend (strongly) on characteristics of unreliable channel (lose, corrupt, reorder data?)

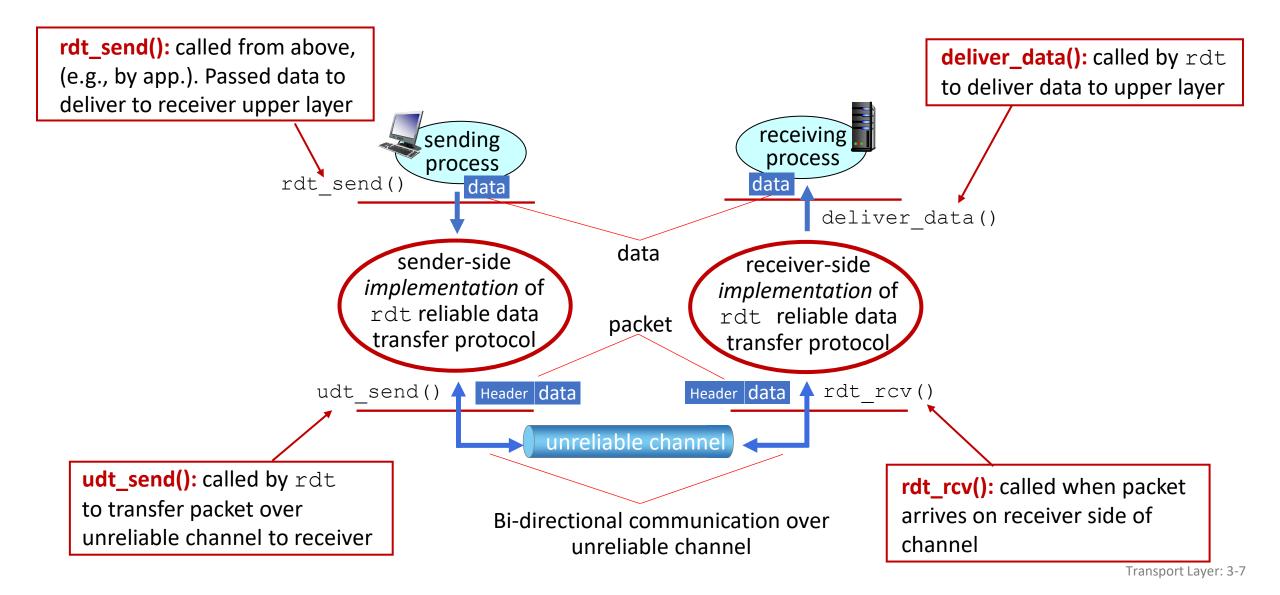

reliable service implementation

Sender, receiver do *not* know the "state" of each other, e.g., was a message received?

unless communicated via a message

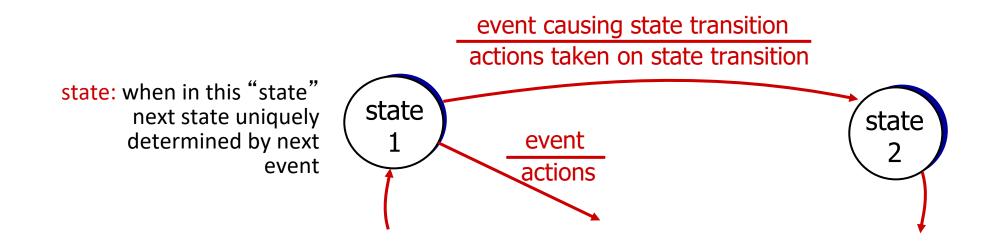

Reliable data transfer protocol (rdt): interfaces

Reliable data transfer: getting started

We will:

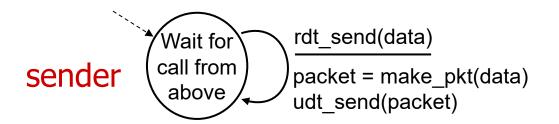

- incrementally develop sender, receiver sides of reliable data transfer protocol (rdt)
- consider only unidirectional data transfer
 - but control info will flow in both directions!
- use finite state machines (FSM) to specify sender, receiver

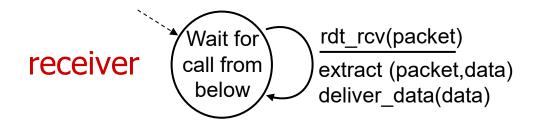

rdt1.0: reliable transfer over a reliable channel

- underlying channel perfectly reliable
 - no bit errors
 - no loss of packets
- separate FSMs for sender, receiver:
 - sender sends data into underlying channel
 - receiver reads data from underlying channel

rdt2.0: channel with bit errors

- underlying channel may flip bits in packet
 - checksum (e.g., Internet checksum) to detect bit errors
- *the* question: how to recover from errors?

How do humans recover from "errors" during conversation?

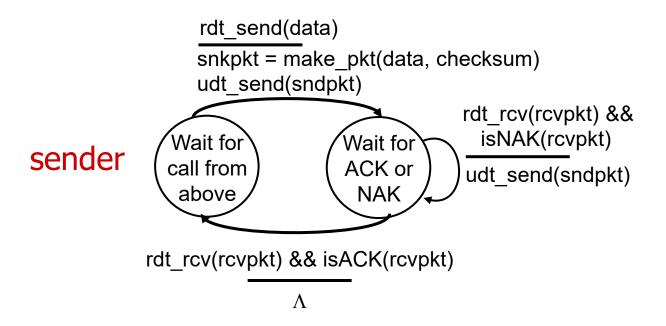

rdt2.0: channel with bit errors

- underlying channel may flip bits in packet
 - checksum to detect bit errors
- *the* question: how to recover from errors?
 - acknowledgements (ACKs): receiver explicitly tells sender that pkt received OK
 - negative acknowledgements (NAKs): receiver explicitly tells sender that pkt had errors
 - sender *retransmits* pkt on receipt of NAK

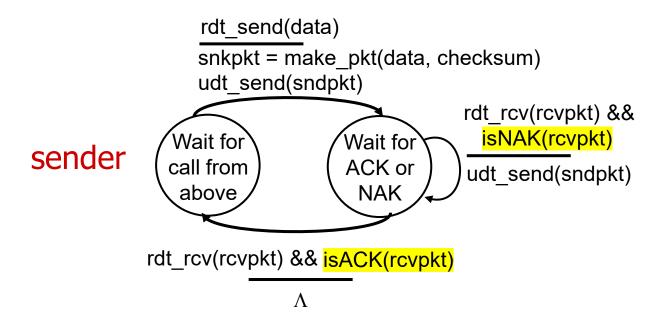

stop and wait

sender sends one packet, then waits for receiver response

rdt2.0: FSM specifications

rdt2.0: FSM specification

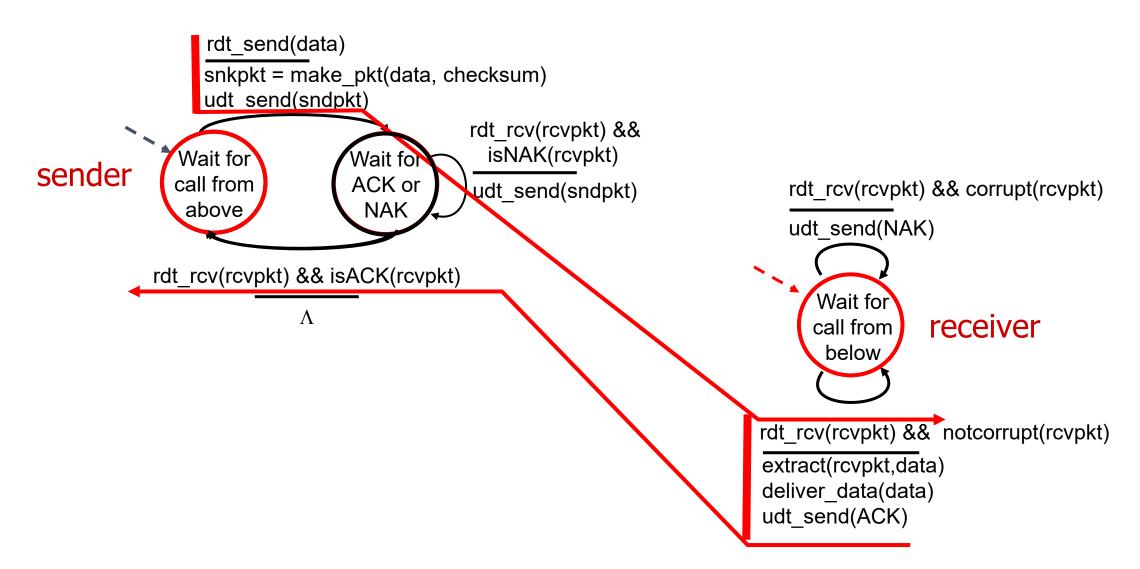

Note: "state" of receiver (did the receiver get my message correctly?) isn't known to sender unless somehow communicated from receiver to sender

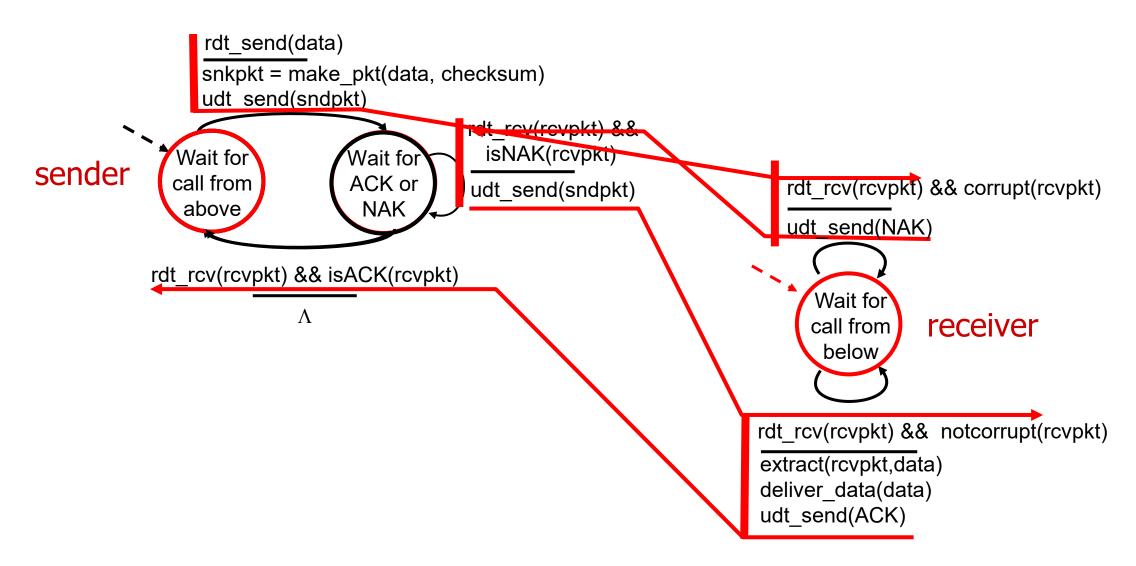

that's why we need a protocol!

rdt2.0: operation with no errors

rdt2.0: corrupted packet scenario

rdt2.0 has a fatal flaw!

what happens if ACK/NAK corrupted?

- sender doesn't know what happened at receiver!
- can't just retransmit: possible duplicate

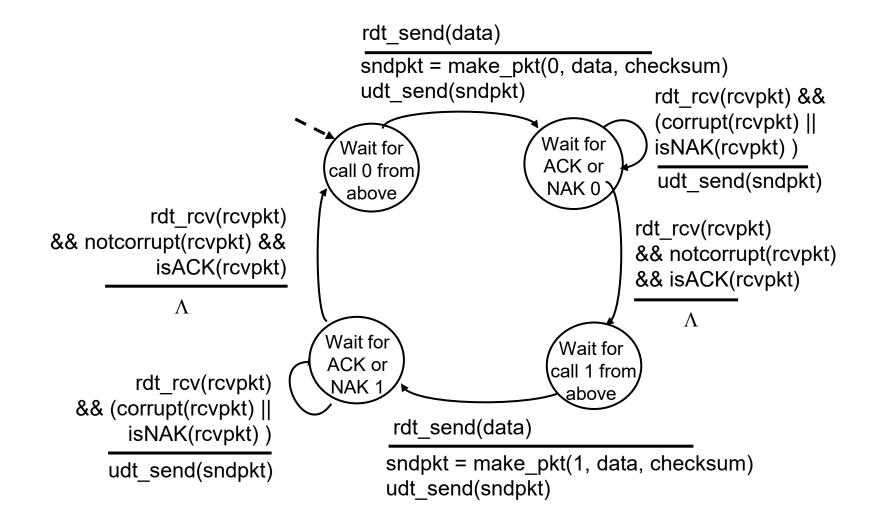

handling duplicates:

- sender retransmits current pkt if ACK/NAK corrupted
- sender adds sequence number to each pkt
- receiver discards (doesn't deliver up) duplicate pkt

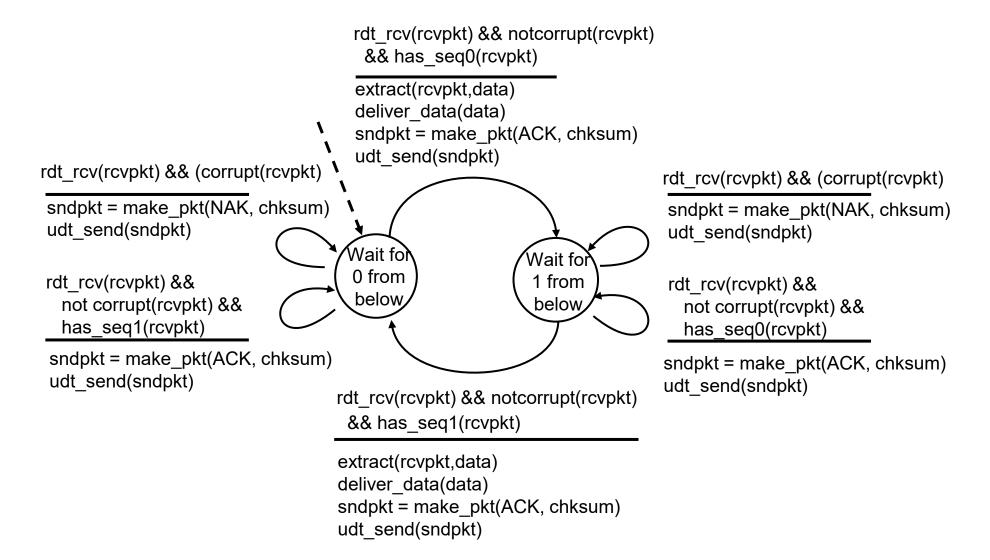

stop and wait

sender sends one packet, then waits for receiver response

rdt2.1: sender, handling garbled ACK/NAKs

rdt2.1: receiver, handling garbled ACK/NAKs

rdt2.1: discussion

sender:

- seq # added to pkt
- two seq. #s (0,1) will suffice. Why?
- must check if received ACK/NAK corrupted
- twice as many states
 - state must "remember" whether "expected" pkt should have seq # of 0 or 1

receiver:

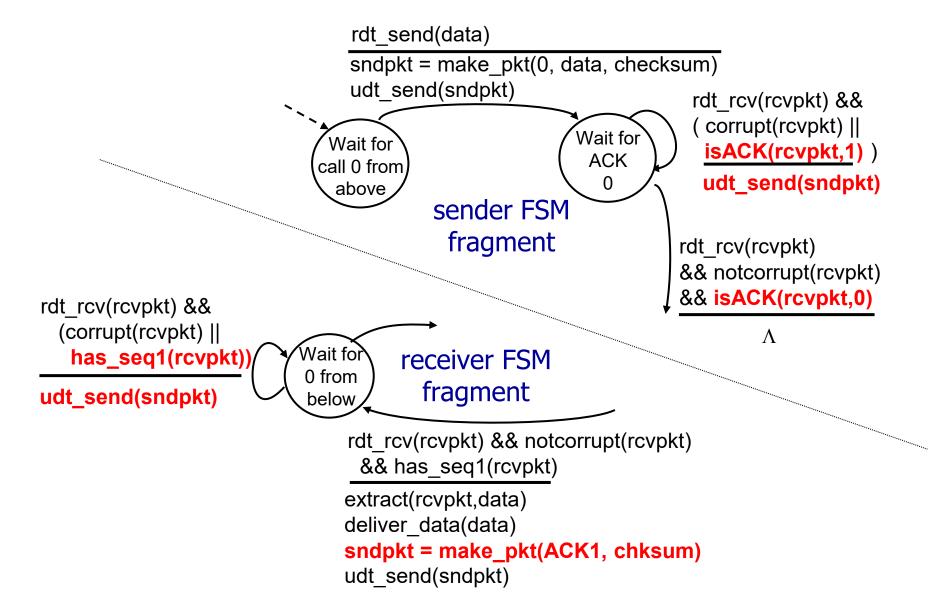

- must check if received packet is duplicate
 - state indicates whether 0 or 1 is expected pkt seq #
- note: receiver can not know if its last ACK/NAK received OK at sender

rdt2.2: a NAK-free protocol

- same functionality as rdt2.1, using ACKs only
- instead of NAK, receiver sends ACK for last pkt received OK
 - receiver must explicitly include seq # of pkt being ACKed
- duplicate ACK at sender results in same action as NAK: retransmit current pkt

As we will see, TCP uses this approach to be NAK-free

rdt2.2: sender, receiver fragments

rdt3.0: channels with errors and loss

New channel assumption: underlying channel can also lose packets (data, ACKs)

checksum, sequence #s, ACKs, retransmissions will be of help ...
 but not quite enough

Q: How do *humans* handle lost sender-to-receiver words in conversation?

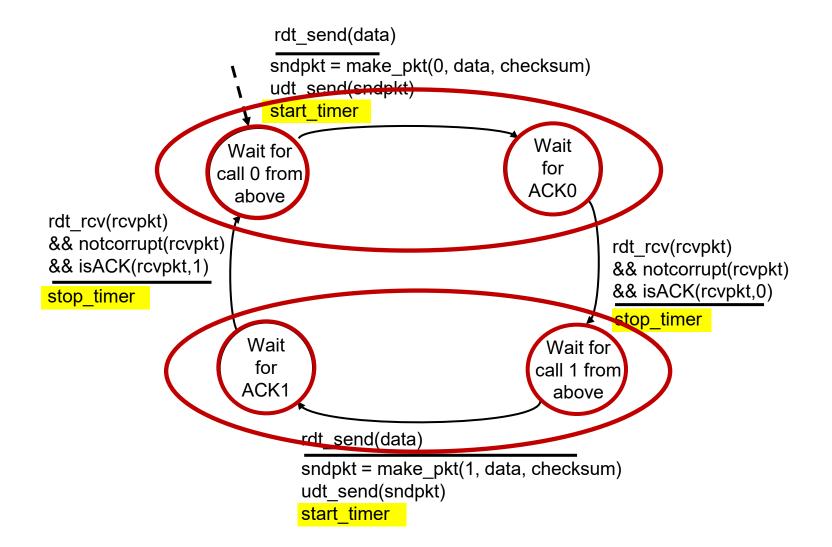

rdt3.0: channels with errors and loss

Approach: sender waits "reasonable" amount of time for ACK

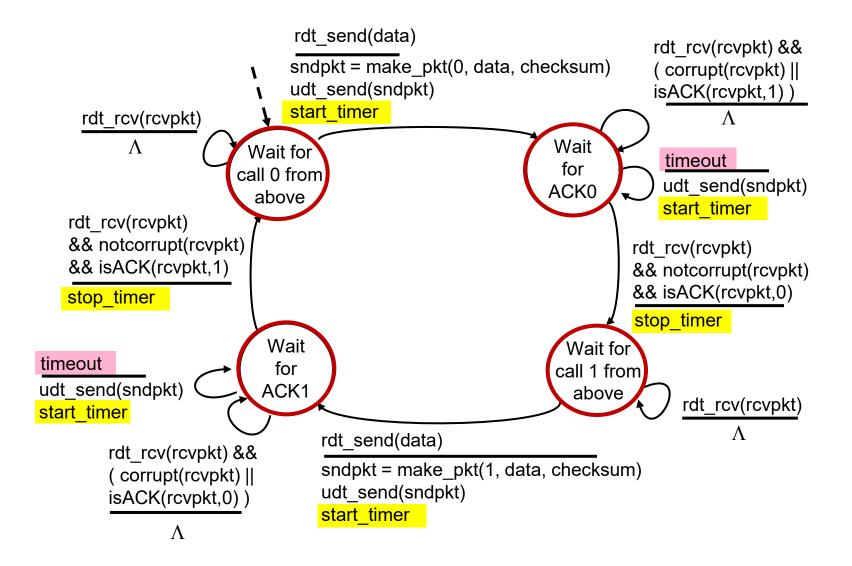

- retransmits if no ACK received in this time
- if pkt (or ACK) just delayed (not lost):
 - retransmission will be duplicate, but seq #s already handles this!
 - receiver must specify seq # of packet being ACKed
- use countdown timer to interrupt after "reasonable" amount of time

timeout

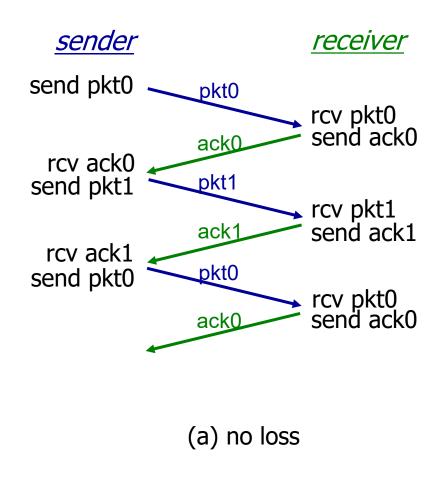

rdt3.0 sender

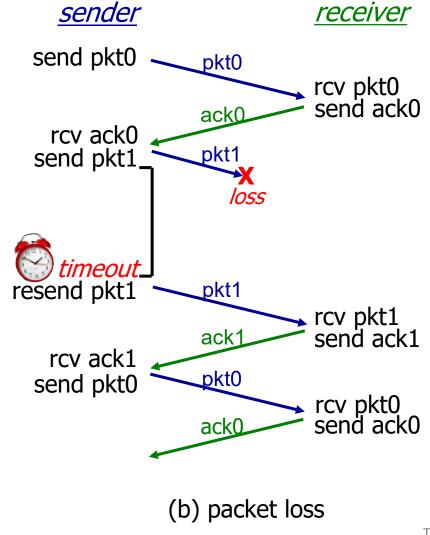

rdt3.0 sender

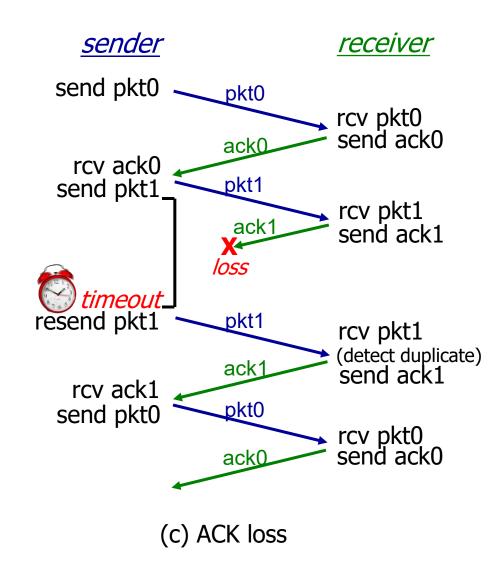

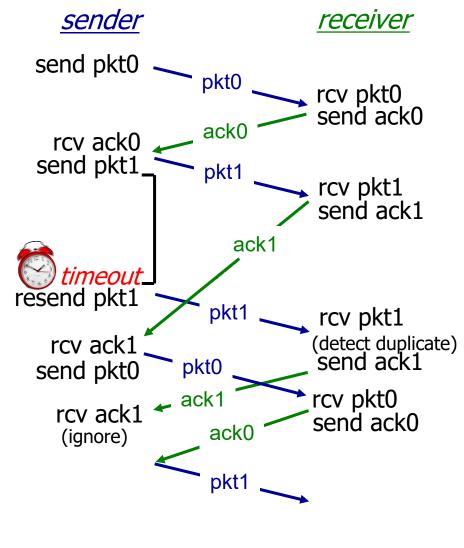

rdt3.0 in action

rdt3.0 in action

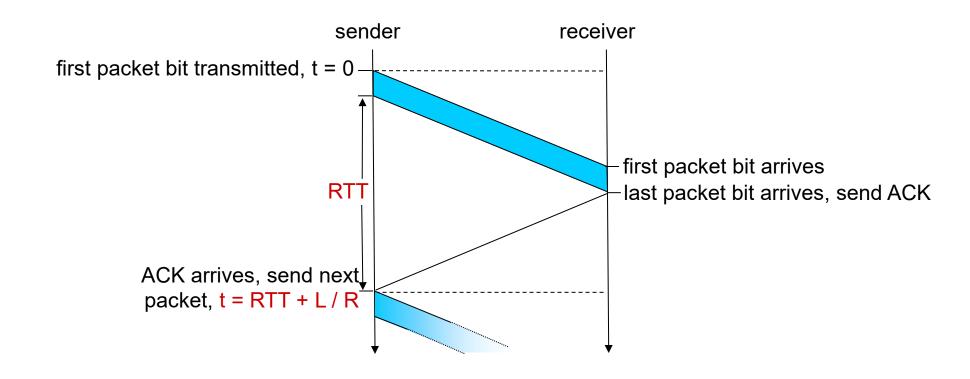

(d) premature timeout/ delayed ACK

Performance of rdt3.0 (stop-and-wait)

- *U* _{sender}: *utilization* fraction of time sender busy sending
- example: 1 Gbps link, 15 ms prop. delay, 8000 bit packet
 - time to transmit packet into channel:

$$D_{trans} = \frac{L}{R} = \frac{8000 \text{ bits}}{10^9 \text{ bits/sec}} = 8 \text{ microsecs}$$

rdt3.0: stop-and-wait operation

rdt3.0: stop-and-wait operation

$$U_{\text{sender}} = \frac{L/R}{RTT + L/R}$$

$$= \frac{.008}{30.008}$$

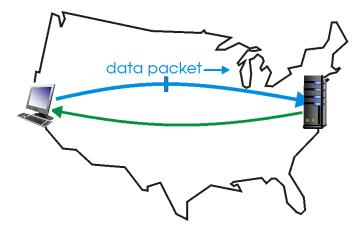

$$= 0.00027$$

- rdt 3.0 protocol performance stinks!
- Protocol limits performance of underlying infrastructure (channel)

rdt3.0: pipelined protocols operation

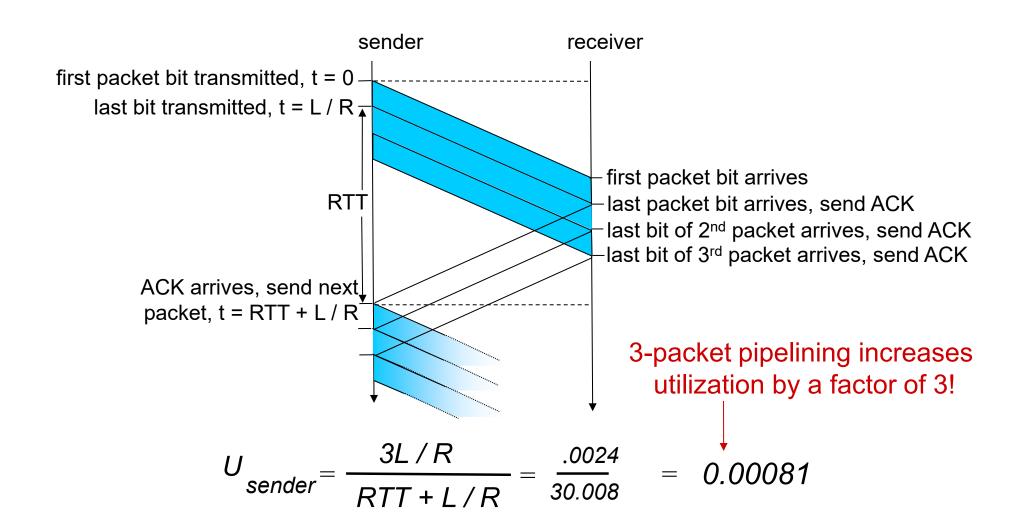

pipelining: sender allows multiple, "in-flight", yet-to-be-acknowledged packets

- range of sequence numbers must be increased
- buffering at sender and/or receiver

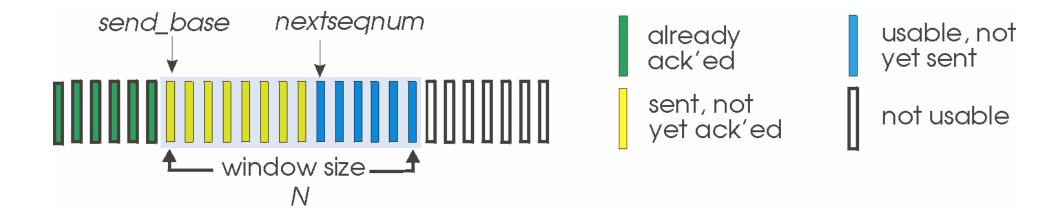

(a) a stop-and-wait protocol in operation

Pipelining: increased utilization

Go-Back-N: sender

- sender: "window" of up to N, consecutive transmitted but unACKed pkts
 - k-bit seq # in pkt header

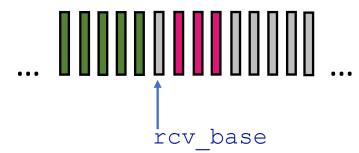

- cumulative ACK: ACK(n): ACKs all packets up to, including seq # n
 - on receiving ACK(n): move window forward to begin at n+1
- timer for oldest in-flight packet
- timeout(n): retransmit packet n and all higher seq # packets in window

Go-Back-N: receiver

- ACK-only: always send ACK for correctly-received packet so far, with highest in-order seq #
 - may generate duplicate ACKs
 - need only remember rcv base
 - on receipt of out-of-order packet:
 - can discard (don't buffer) or buffer: an implementation decision
 - re-ACK pkt with highest in-order seq #

Receiver view of sequence number space:

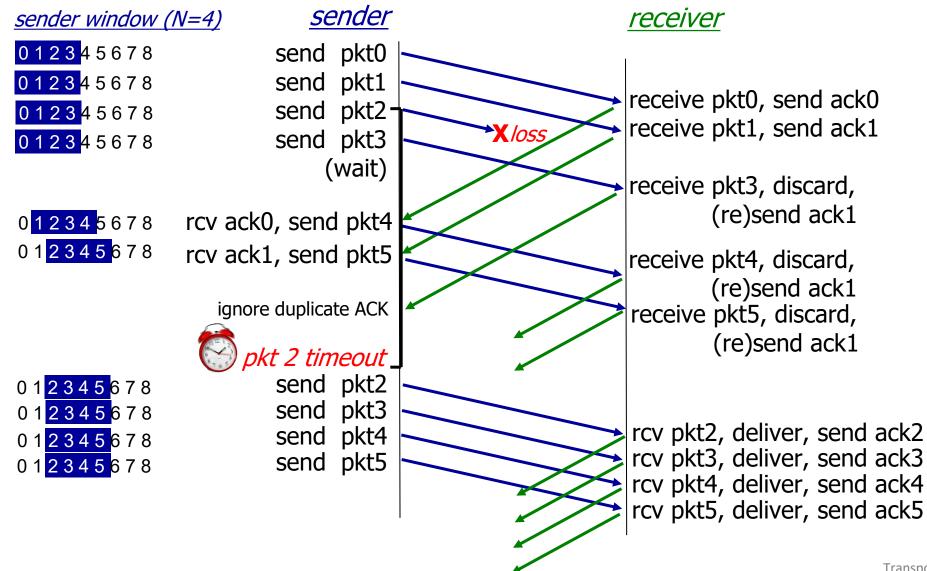

received and ACKed

Out-of-order: received but not ACKed

Not received

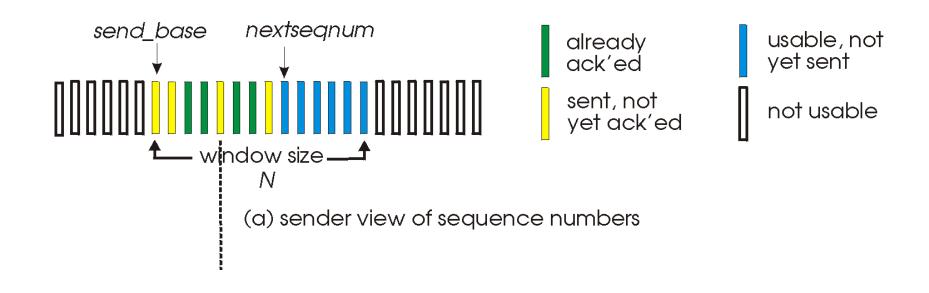

Go-Back-N in action

Selective repeat: the approach

- pipelining: multiple packets in flight
- receiver individually ACKs all correctly received packets
 - buffers packets, as needed, for in-order delivery to upper layer
- •sender:
 - maintains (conceptually) a timer for each unACKed pkt
 - timeout: retransmits single unACKed packet associated with timeout
 - maintains (conceptually) "window" over N consecutive seq #s
 - limits pipelined, "in flight" packets to be within this window

Selective repeat: sender, receiver windows

Selective repeat: sender and receiver

sender

data from above:

if next available seq # in window, send packet

timeout(*n*):

resend packet n, restart timer

ACK(n) in [sendbase,sendbase+N-1]:

- mark packet n as received
- if n smallest unACKed packet, advance window base to next unACKed seq #

receiver

packet n in [rcvbase, rcvbase+N-1]

- send ACK(n)
- out-of-order: buffer
- in-order: deliver (also deliver buffered, in-order packets), advance window to next not-yetreceived packet

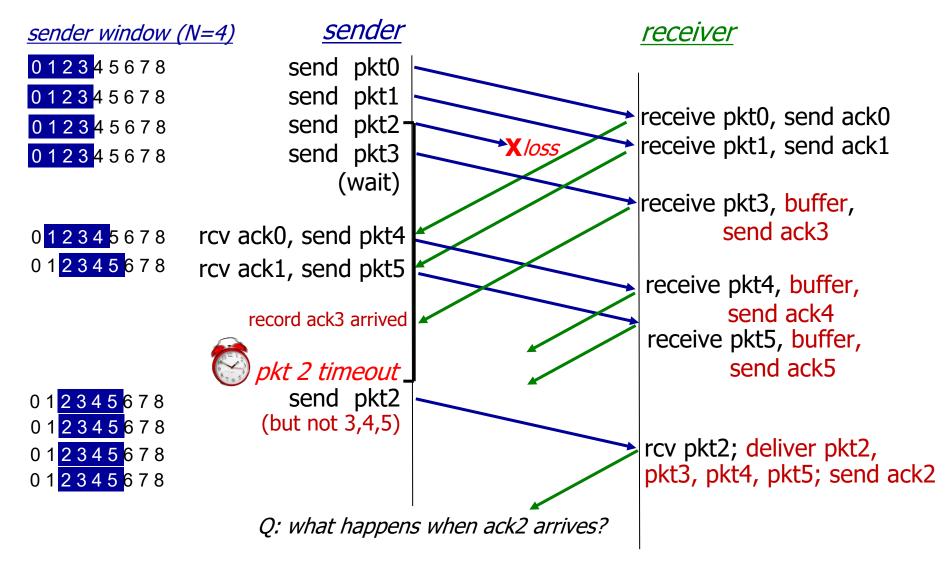

packet n in [rcvbase-N,rcvbase-1]

ACK(n)

otherwise:

ignore

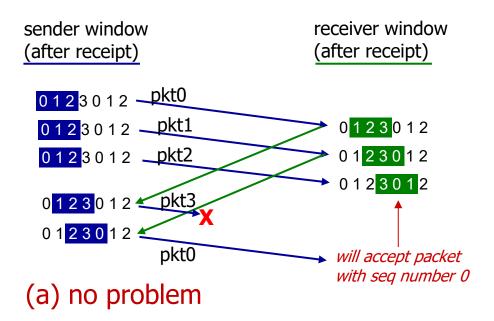

Selective Repeat in action

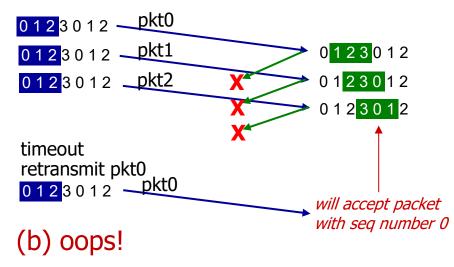

Selective repeat: a dilemma!

example:

- seq #s: 0, 1, 2, 3 (base 4 counting)
- window size=3

Selective repeat: a dilemma!

example:

- seq #s: 0, 1, 2, 3 (base 4 counting)
- window size=3

Q: what relationship is needed between sequence # size and window size to avoid problem in scenario (b)?
